

I must not forget, however, that in the framework of my problem "wealth-income" the relevant entry is the entry in the property holding (wealth tax paying) class,

which presuppose accumulation of wealth of a minimum size.

the pattern of hierarchical management in the Simon's model must be a sediment of entire evolution in time in which entry and exit of managers (employees) is the basis.

[Not very hard in the model advances, this explains the pyramidical structure. Here it seems that the cross-section pattern is the prior pattern and the time evolution has to adjust to it. But is it so?]

The increase in the relative number of qualified people.

as a regular phenomenon through the generations is a case of allometry

assuming that the various parts of the population increase exponentially, at different rates [The total population can't, then, increase exponentially!] perhaps logistic pattern, or Gompertz function? ?

Success and individual life is

the wild des ges verbreiten Dimensionen !!
